1

Loudspeaker having a composite diaphragm structure

The invention relates to a loudspeaker provided with a chassis, a movable body, a resilient suspension for guiding the movable body with respect to the chassis along a translation axis, and an electric actuator for driving the movable body along the translation axis.

5

Speakers of such a type are generally known; e.g. PCT Patent Application WO 96/14722 discloses such a loudspeaker. This known loudspeaker has a frame, a membrane and an electromagnetic driving unit. The membrane is formed by a conical body and has an outer circumferential edge and an inner circumferential edge. The driving unit is provided with a stationary part and a movable part. The stationary part includes a permanent magnet and a magnetic yoke and is secured to the frame. The movable part includes a voice coil and a cylindrical coil support. At its outer circumferential edge, the membrane is connected to the frame by means of a flexible suspension and, at its inner circumferential edge, it is adhered to the coil support, which in its turn is connected to the frame by means of a spider.

10
15

The conical membrane of the known loudspeaker has a certain height in order to obtain sufficient stiffness. The membrane must have a certain minimal stiffness in order to be able to move like a piston, not only for low frequency reproduction but for the whole or at least the larger part of the audio spectrum.

20

For this reason, there arise problems relating to the speaker's performance when a shallow speaker, i.e. a speaker having a small height, is required in certain applications.

25

It is an object of the invention to improve the known loudspeaker in such a way that it can be given a small height without degrading its sound performance.

This object is achieved with the loudspeaker according to the invention, which is provided with a chassis, a movable body, a resilient suspension for guiding the movable body with respect to the chassis along a translation axis, and an electric actuator for driving

2

the movable body along the translation axis, which movable body has a diaphragm structure comprising a centrally situated dome-shaped diaphragm and a decentralized cone-shaped diaphragm concentrically arranged with respect to the dome-shaped diaphragm, which cone-shaped diaphragm has a back portion and a front portion which is wider than the back
5 portion, wherein both diaphragms are attached to each other near the back portion of the cone-shaped diaphragm, the cone-shaped diaphragm enveloping the dome-shaped diaphragm, and wherein the resilient suspension comprises a resilient element connecting the diaphragm structure to the chassis near the back portion of the cone-shaped diaphragm, and a further resilient element connecting the diaphragm structure to the chassis near the front portion of
10 the cone-shaped diaphragm.

Thus, the loudspeaker according to the invention has a diaphragm structure which is composed of an outwardly convex, particularly dome-shaped, diaphragm and a cone-shaped diaphragm situated around the other diaphragm. This makes it possible to give the diaphragm structure of the movable body sufficient stiffness to prevent an undesired
15 break-up, i.e. bending wave resonances, during mid and high-frequency reproduction in relatively flat loudspeaker constructions. In principle, a cone-shaped diaphragm known per se may be used. The same applies to the dome-shaped diaphragm. A rigid dome-shaped diaphragm known per se may be used. Such diaphragms are known, for instance, from US-A 3,925,626. The loudspeaker according to the invention can be driven by a usual audio
20 transformer of an amplifier system known per se.

A favorable embodiment of the loudspeaker according to the invention has the characteristic feature that the electric actuator comprises a stationary part which is secured to the chassis or to a stationary element fixed to the chassis and further comprises a translatable part which is secured to the dome-shaped diaphragm. Due to this feature, the translatable part
25 of the electric actuator extends into the space enveloped by the dome-shaped diaphragm.

It is to be noted that said US-A 3,925,626 discloses an all-frequency loudspeaker which has a domed diaphragm instead of the usual cone diaphragm of the prior art in order to get, inter alia, a high-fidelity sound. Secured to the underside of the diaphragm is a form which extends downwards into an air gap formed by a pole piece and a top ring of a
30 magnet system and on which a voice coil has been wound. The device formed by the diaphragm and the form is suspended from a framework by means of a resilient suspension secured to both the diaphragm and the framework and a resilient support secured to both the form and the framework. A disadvantage of this known loudspeaker is its height, which has to be substantial in order to provide sufficient distance between the lower resilient support

3

and the topring to realize the required travel of the diaphragm. Contrary to the known devices, the loudspeaker according to the invention has no suspension means secured to the coil support, and thus does not have the above-described disadvantage.

In a practical embodiment of the loudspeaker according to the invention, the back portion of the cone-shaped diaphragm includes an inner circumferential edge to which an outer circumferential rim of the dome-shaped diaphragm is connected, said edge and rim being preferably attached to each other by means of an adhesive, such as a glue. In this context it is also preferred to connect an inner circumferential brim of the resilient element of the resilient suspension to the inner circumferential edge of the cone-shaped diaphragm and/or to the outer circumferential rim of the dome-shaped diaphragm. This can also be realized by means of a suitable adhesive.

In another practical embodiment, the stationary part includes a magnetic yoke with a permanent magnet and the translatable part includes a coil support with a voice coil, which coil extends in an air gap of the magnetic yoke and has a coil axis coinciding with the translation axis of the movable body.

It is to be noted that the loudspeaker according to the invention is suitable for sound reproduction in hifi, home, automotive, TV and multimedia systems and, as already indicated, is particularly suitable for applications having very small built-in depths.

The invention also relates to a diaphragm structure intended for use in the loudspeaker according to the invention. Particularly, the diaphragm structure according to the invention has the characterizing feature that it is composed of a central dome-shaped diaphragm and a cone-shaped diaphragm concentrically arranged with respect to the dome-shaped diaphragm. For a further description, reference is made to claim 6.

The invention further relates to a loudspeaker unit comprising the loudspeaker according to the invention and also comprising a housing accommodating the loudspeaker.

It is noted in relation to the claims that various combinations of characteristic features defined in the claims are possible.

The above-mentioned and other aspects of the invention are apparent from and will be elucidated, by way of non-limitative examples, with reference to the embodiment described hereinafter.

In the drawings:

Figure 1 shows an embodiment of the loudspeaker according to the invention in a diagrammatic cross-section, and

Figure 2 is a perspective elevational view of the loudspeaker of Fig. 1 in an exploded view.

5

The electrodynamic loudspeaker according to the invention, shown in the Figures, comprises a chassis 2, a movable body 4 and an electromagnetic actuator 6. For forming a loudspeaker unit according to the invention, the loudspeaker may be
10 accommodated in a housing. To this end, the chassis 2 may be fixed in an appropriate opening in a wall of this housing. In Fig. 1, the housing is shown diagrammatically by means of a wall section 1 in broken lines.

The movable body 4 has a three-dimensional diaphragm structure comprising a central dome-shaped diaphragm 8 and a cone-shaped diaphragm 10 concentrically arranged
15 with respect to the dome-shaped diaphragm 8. The dome-shaped diaphragm 8 may be made of a metal, such as aluminium; reinforced plastics; pressed paper; or any other suitable material. The diaphragm 8 has a sufficient stiffness and may be provided with a central opening 8a covered by a dust cap 9 of any suitable material, such as paper, plastics, or textile. The cone-shaped diaphragm 10 may be made of pressed paper, carbon fiber, polyglass,
20 aluminium, or any other suitable material. The cone-shaped diaphragm 10 has a back portion 10_b and a front portion 10_f which is wider than the back portion 10_b. The dome-shaped diaphragm 8 and the cone-shaped diaphragm 10 are mutually secured at the back portion 10_b. For this reason, the cone-shaped diaphragm 10 has an inner circumferential edge 10_i, while the dome-shaped diaphragm 8 has a corresponding outer circumferential rim 8_o. The edge 10_i
25 and the rim 8_o preferably have round cross-sections so that the edge 10_i and the rim 8_o fit each other. The edge 10_i and the rim 8_o are preferably glued to each other.

The loudspeaker further comprises a resilient suspension for suspending the movable body 4 from the chassis 2 and for guiding the movable body along a translation axis T. The suspension includes a first resilient element 12a and a second resilient element 12b.
30 The first resilient element 12a is a ring-like spider, an inner circumferential brim 12a_i of which is attached to the edge 10_i and/or the rim 8_o and an outer circumferential brim 12a_o is attached to the chassis 2. A glue may be used for both attachments. The spider 12a may be a known flexible corrugated body and ensures that the movable body 4 can perform well-defined translation movements with respect to the chassis 2.

PHNL031033

PCT/IB2004/051413

5

The second resilient element 12b has a roll structure known per se and is formed, for example, from a bent rubber or foam annular strip. On its outer circumference, the second element 12b is secured, for example glued, to the chassis 2 and on its inner circumference to an outer circumferential edge 10_o of the cone-shaped membrane 10.

- 5 The actuator 6 essentially comprises two elements, namely a stationary actuator part 6a which is fixed to the chassis 2 and a translatable actuator part 6b which is connected to the movable body 4. One of the actuator parts - in this example the part 6a - is provided with a permanent magnet 13, in this example annular in shape and axially polarized, and the other actuator part - in this example the part 6b - is provided with a magnet coil 14.
- 10 The permanent magnet 13 is formed from a neodymium-iron-boron alloy and forms a magnetic yoke 13a with soft iron portions of the stationary actuator part 6a, which yoke defines an air gap 16. The magnet coil 14, being a cylindrical coil, also referred to as voice coil, is situated on a coil support 14a, being a sleeve in this example, which is fixed to the dome-shaped diaphragm 8. A lead wire 17 connects the coil 14 by means of a connector 18
- 15 which is adhered to the chassis 2. When energizing the coil 14, both actuator parts 6a, 6b magnetically co-operate with each other over the air gap 16 for generating a driving force on the movable body 4 parallel to the translation axis T and thus on the dome-shaped diaphragm 8 and the cone-shaped diaphragm 10.

- It is to be noted that the invention is not limited to the embodiment shown. For
- 20 example, the dome-shaped diaphragm and the cone-shaped diaphragm may be formed as an integral combination, thus comprising or consisting of a single diaphragm structure. Moreover, the loudspeaker unit may not only comprise one or more speakers but also one or more passive radiators or bass reflex ports. Furthermore, the loudspeaker according to the invention is not limited to a certain power. For acoustical sound tuning purposes, the dome-
- 25 shaped diaphragm may be provided with perforations and/or a coating. For the same purposes, the outer circumferential rim of the dome-shaped diaphragm does not need to be a back portion of the dome-shaped diaphragm, but may be a rim parallel to the back portion.
